Lab 6
Reading Inputs with Logic Operations

October 20, 2022

ECE 425L

Assigned by: Neda Khavari

Written By: Cristian Robles & Pathum Addarapathirana

#### **Introduction:**

In lab 6 we are introduced to using external peripherals to get inputs and execute them on the LPC2148. While reading the external peripherals we practice reading signals through port pins, using logic operations, and using the Keil simulator to simulate inputs.

# **Procedure:**

Equipment Used

- Keil uVision4
- Keil Debugger
- LPC2148 Education Board

# Description of Procedure

1. Set up startup code. This is the code needed to start the lab that includes the header below and the mystatup code given in lab 3.

```
GLOBAL Reset Handler
AREA mycode, CODE, Readonly
Reset Handler ;this label is necessary for the first line of your code
```

2. In the next part of our code we declare our constants and name some registers using the EQU and RN directives. This allows for more readable code

```
0x00004000
               EQU
6 Bitl4
    PINSEL0
               EQU
                       0xE002C000
  IOOPIN
               EQU
                      0xE0028000
   IOOSET
               EQU
                      0XE0028004
10 IOODIR
               EQU
                       0xE0028008
               EQU 0XE002800C
11 IOOCLR
12 A_var
               RN
13 B_var
               RN
14 C_var
               RN
                       8
15
16 Reset
17
               ;Initially Assigning A & B
18
               MOV B_var, #0
19
               MOV A_var, #10
20
               MOV C_var, #0
```

3. In the next part of the code we use the defined constants to set the pins as GPIO and set the direction of the signal for them as well. All pins except 14 were outputs because it is also connected to the button that we use as an input

```
; Selecting funcion as GPIO by writing all zer
24

After the count for the number of presses stored in B\_var was higher than 10 we were able to turn off all the LEDs connected to pins 8-15 successfully

# **Questions:**

Question 1: What logic level does the microcontroller read from its pin P0.14 when the switch (labeled as SW1 in the figure) is not pressed? What signal will be generated on pin P0.14 when the switch is pressed?

When the pin is not pressed the signal generated on pin 14 is 1. Once it is pressed the signal generated becomes 0

Question 2: You need to configure the pin P0.14 as input pin or output pin so that the microcontroller can read the status of the switch? (Hint: input or output is from the perspective of the microcontroller.)

For the microcontroller to be able to read the pin we need to configure the pin as an input

Question 3: What do you do if you need to clear bit 14 of the I/O direction register IO0DIR? Note that IO0DIR is assigned with a memory address therefore it can be treated as a memory location. Write a code segment to do that.

LDR r0, 0x0000BF00 LDR r1,=IO0DIR STR r0,[r1]

# Question 4: Should you check or uncheck the pin P0.14 to simulate a button pressing action?

To simulate the button being pressed within the Keil Debugger you would uncheck the box

# **Conclusion:**

In conclusion, we were able to successfully read input pin values on pin 14 on the LPC 2148 using logic operations. Since the pin is connected to both an LED and a button we had to take extra steps to make sure the light was an output pin when it needed to be and it was an input pin when it needed to be. For this we had to check constantly for when it was pressed and make sure to reset the pin to an input after the corresponding LEDs turned on. One thing that could improve this lab would be adding a debouncer to the button as on the physical board one press would sometimes register multiple presses. This project furthered our knowledge of GPIO and logic operations.
